Environmental Quality of the Neuse River, North Carolina During Summer 1998: Data Summary

1. Introduction

This report presents data generated from samples of water, sediment, and biota collected in the Neuse River, NC during the summer of 1998. The sampling effort is part of a joint study, initiated by the National Oceanic and Atmospheric Administration (NOAA) and the U.S. Environmental Protection Agency (U.S. EPA), to assess the health of southeastern estuaries by coordinating two nationwide environmental monitoring efforts: NOAA's National Status and Trends program (NS&T) and U.S. EPA's Environmental Monitoring and Assessment Program (EMAP). The joint coastal research and monitoring program retains the EMAP sampling design, which includes randomly selected sites distributed over various biogeographical provinces of the U.S. The probability-based sampling design makes it possible to assess the status of selected indicators of ecological health on a regional basis with known confidence.

The EMAP Carolinian Province encompasses estuaries from Cape Henry, VA to St. Lucie Inlet, FL. Full province-wide assessments of Carolinian Province estuaries were conducted during the summers of 1994 and 1995 (Hyland et al. 1996; Hyland et al. 1998). During the summers of 1996 and 1997, the EMAP random sampling design was applied again, although sampling was limited to estuaries in the North Carolina portion of the province due to funding constraints. A comprehensive analysis of the quality of North Carolina estuaries, based on all four years of sampling (1994-1997), has been completed and submitted for publication (Hyland et al, In Review). The summer 1998 sampling effort was focused on a site-intensive assessment of environmental conditions in the Neuse River, NC. There is a growing concern that human-induced inputs associated with unprecedented growth in this area over the last 50 years may have contributed to long-term degradation in water quality in the Neuse River Estuary. Potential sources of pollution include organic wastes from hog and chicken operations, agricultural run-off of pesticides, polynuclear aromatic hydrocarbons (PAHs) from road run-off and boat activities, and sewage from septic tanks and sewage treatment facilities. Data collected from this study also will be used to support the Mid-Atlantic Integrated Assessment (MAIA 1999). MAIA is an inter-agency, multi-disciplinary program focused on monitoring and research in the mid-Atlantic region of the eastern U.S., which includes watersheds of the Delaware and Chesapeake Bays, Albemarle-Pamlico Sound, and the Delmarva Coastal Bays.

The purpose of the following report is to provide a presentation of the data resulting from the 1998 Neuse River survey. While brief descriptions of methods are included, interpretive analyses and related conclusions are purposely omitted to stay within the theme of a data summary report. Such treatments of the data will be included in subsequent publications in the peer-reviewed literature.

2. Sampling Methods & Results

Twenty randomly located stations (Figure 1; Table 1) were sampled in the Neuse River between July 13 and July 16, 1998 by scientists from the NOAA/NOS Center for Coastal Monitoring and Assessment (CCMA) in Charleston, SC; the NOAA/NOS Center for Coastal

Environmental Health and Biomolecular Research (CCEHBR) in Charleston, SC; the NOAA/NOS Center for Coastal Fisheries and Habitat Research (CCFHR) in Beaufort, NC; the SC Department of Natural Resources; and the University of North Carolina – Wilmington. Station locations were determined by dividing the lower Neuse River (mouth to tidal fresh portion) into five equidistant segments, and then randomly selecting four station locations within each river segment. This method was used to produce probability-based samples for estimates of the proportion of estuarine area falling within specified ranges of environmental indicators, and to estimate these quantities with known confidence.

Two teams of three to four crew members each conducted the sampling from small trailerable boats. At each station, samples and in-situ measurements were taken for characterization of: (1) general habitat conditions (depth, physical properties of water, sediment silt-clay content, organic carbon content of sediment); (2) potential pollution exposure (sediment contaminants, sediment toxicity, ammonia in sediment porewater, and low dissolved oxygen conditions in the water column); (3) biotic conditions (diversity and abundances of macrofaunal species); and (4) nutrient loading in water (chlorophyll, phaeophytin, total suspended solids, particulate carbon, particulate and dissolved nitrogen, and particulate and dissolved phosphorus).

2.1 Water

At each station, depth and physical properties of water (dissolved oxygen, temperature, pH, and salinity) were measured instantaneously in surface, near-bottom, and (optionally) mid-depth waters using a Hydrolab DataSonde® 3 multiprobe data logger. When station depth was less than 1 meter, only mid-depth readings were taken. Where possible, readings were recorded on the downcast and upcast, yielding a pair of measurements at each depth for a given station (Table 2).

Water samples were collected at each station for nutrient analysis using a General Oceanics GO-FLO non-metallic water sampling bottle. Samples were collected at near-surface and near-bottom depths for stations with depths ≥ 3 m. For stations with depth < 3 m, one sample was collected at mid-depth only. Each sample consisted of 3-5 L of water, which was stored in a clean 1-gal. plastic container, held on ice in the dark and filtered within four hours, wherever possible. Results of water-column nutrient analyses are shown in Table 3.

2.2 Sediment

Samples of bottom sediments were obtained at each station using a 0.04m² Young grab sampler. The upper 2 cm of sediment from multiple grabs were homogenized and placed into sample jars for subsequent analysis of silt-clay, total organic carbon, and porewater unionized ammonia nitrogen (Table 4); metals and acid volatile sulfide (AVS) (Table 5); polynuclear aromatic hydrocarbons (PAHs) (Table 6); polychlorinated biphenyls (PCBs) (Table 7); pesticides (Table 8); and sediment toxicity (Table 9).

Sediments were analyzed for contaminants according to the procedures referenced in Table 10. Included in Table 10 are minimum detection limits for each analyte, based on a sample size of 0.5 g dry weight. The actual sample-specific method detection limits (MDLs) are reported in Tables 5 – 8.

Toxicity of bottom sediments was evaluated using two different assays: the Microtox® solid-phase assay with the photoluminescent bacterium *Vibrio fischeri*, and the ten-day solid-phase test for survival of the marine amphipod *Ampelisca abdita*. The Microtox® test provides a sublethal measure of toxicity based on attenuation of light production by *V. fischeri* cells due to exposure to the sediment sample (Bulich 1979; Ross et al. 1991; Microbics 1992 a and b). Ringwood et al. (1995, 1997) demonstrated a strong inverse relationship between Microtox® EC₅₀ – the sediment concentration that reduced light production by 50% relative to a nontoxic reagent control blank – and percent silt-clay content of the sediment. Hence, for the Microtox® assay, samples with silt-clay content ≥ 20% were classified as toxic if EC₅₀ values were ≤ 0.2% sediment; samples with silt-clay < 20% were classified as being toxic if EC₅₀ values were ≤ 0.5% sediment. EC₅₀ values were corrected for percent water content and reported as dry-weight concentrations. For the *A. abdita* test (ASTM 1993), sediments were considered toxic if *A. abdita* mean survival relative to control was less than 80% and survival was significantly different from control survival (*t*-test, $\alpha = 0.05$).

Three replicate sediment grabs also were collected from each station and live-sieved in the field with a 0.5-mm mesh screen. Material retained on the screen was placed in individual plastic containers and fixed in 10% buffered formalin with rose bengal for identification of benthic infauna in the laboratory (Table 11).

^a Significant *A. abdita* toxicity = survival relative to control < 80% and significantly different from control survival ($\alpha = 0.05$).

^b Significant Microtox® toxicity = EC₅₀ ≤ 0.2% if silt-clay ≥ 20%, or EC₅₀ ≤ 0.5% if silt-clay < 20%.

^c Calculated EC₅₀ result was greater than the highest test concentration of 10%. Because the accuracy of an EC₅₀ value above 10% is unknown, EC₅₀ values greater than 10% have been reported as 10.000%.

2.3 Demersal Trawls

In addition to water and sediment samples and measurements collected at each station, demersal trawls were conducted at ten stations selected at random from the total of twenty sampling sites. Fishes and invertebrates were collected at each of these 10 stations with a 4.9-m otter trawl (2.5-cm mesh cod end) towed against the tidal current. Two ten-minute tows were attempted at each of the 10 stations, and were conducted after all other sampling at a station was completed. Demersal trawl samples and observations collected from each of these stations included: (1) tissue contaminant samples from target demersal biota; (2) diversity and abundances of demersal species; (3) presence of pathologies in demersal species; and (4) presence of SAV. All demersal organisms captured in each trawl were identified in the field, enumerated (Table 12), and examined for the presence of pathologies (Table 13). On completing these observations, a maximum of up to twenty penaeid shrimp, ten blue crabs, ten Atlantic croaker, and ten spot per station were collected for contaminant analysis of edible tissues. At the time of this writing, the tissue chemistry analyses have not been completed; consequently, those data will be published in a subsequent report.

Table 12. Abundance of demersal taxa collected in trawls.

Table 13. Pathologies observed in demersal trawl biota.

Station	Trawl	Number of Pathologies	Taxon	Pathology Type
CP98410	01	3	<i>Brevoortia tyrannus</i>	Ulcer
CP98410	02	3	<i>Brevoortia tyrannus</i>	Ulcer
CP98411	02	2	<i>Brevoortia tyrannus</i>	Ulcer

3. Acknowledgments

This program was jointly sponsored by EPA and the NOAA National Ocean Service (NOAA/NOS). EPA funds were provided through Interagency Agreement #DW13936394-01 from EPA's National Health and Environmental Effects Research Laboratory (NHEERL), Gulf Ecology Division. NOAA/NOS funds were provided by the Center for Coastal Monitoring and Assessment (CCMA) of the National Centers for Coastal Ocean Science (NCCOS).

We would like to thank the following individuals who made significant contributions to the overall effort:

Program Management and Coordination – Andrew Robertson (NOAA/NOS – NCCOS/CCMA); Kevin Summers, John Macauley (EPA – Gulf Ecology Division); Courtney Hackney (University of NC – Wilmington); Don Hoss (NOAA/NOS – Center for Coastal Fisheries and Habitat Research (CCFHR)); Charles Strobel (EPA – Atlantic Ecology Division).

Contaminant Analyses – Marion Sanders, Erich Strozier, Scott Sivertsen, Aaron Diaz, Katy Chung, Peter Jenkins (NOAA/NOS –Center for Coastal Environmental Health and Biomolecular Research (CCEHBR)).

Benthic Analyses – Carl M. Way, Linda W. Sierke (Barry A. Vittor & Associates, Inc.).

Toxicity Testing – Microtox® assays: Brian Thompson (NOAA/NOS – CCEHBR); *Ampelisca abdita* assays: Trac Laboratories, Inc.

Nutrient Analyses – Lisa Smith (EPA – Gulf Ecology Division).

Field Work – James Daugomah (NOAA/NOS – CCEHBR); Mike Greene (NOAA/NOS – CCFHR); Jude Grimley (University of NC – Wilmington); Steve Kokkinakis (NOAA/NOS – NCCOS/CCMA); Tim Snoots (SC Department of Natural Resources (SCDNR)).
