INTRODUCTION

The Chesapeake Bay region was sampled during August and September, 1999. One aspect of this evaluation was benthic community characterization, which was accomplished via sample collection by National Oceanic and Atmospheric Administration (NOAA) personnel and laboratory and data analysis by Barry A. Vittor & Associates, Inc. (BVA).

The Chesapeake Bay region and 1999 sampling stations are indicated in Figure 1.

METHODS

Sample Collection and Handling

A Young dredge (area = 0.04 m²) was used to collect bottom samples at each of 69 stations located in 23 strata in Chesapeake Bay (Figure 1, Table 1). Macroinfaunal samples were sieved through a 0.5-mm mesh screen and preserved with 10% formalin on ship. Macroinfaunal samples were transported to the BVA laboratory in Mobile, Alabama.

Sediment Analysis

Sediment texture was determined at half-phi intervals using the hydrometer technique for fractions smaller than 44 µm and nested sieves for larger particle fractions. Calculated sediment texture parameters included percent gravel, sand, silt, and clay. Total organic carbon (TOC) content was measured as ash-free dry weight expressed as a percentage.

Macroinfaunal Sample Analysis

In BVA's laboratory, benthic samples were inventoried, rinsed gently through a 0.5 mm mesh sieve to remove preservatives and sediment, stained with Rose Bengal, and stored in 70% isopropanol solution until processing. Sample material (sediment, detritus, organisms) was placed in white enamel trays for sorting under Wild M-5A dissecting microscopes. All macroinvertebrates were carefully removed with forceps and placed in labelled glass vials containing 70% isopropanol. Each vial represented a major taxonomic group (*e.g.* Polychaeta, Mollusca, Arthropoda). All sorted macroinvertebrates were identified to the lowest practical identification level (LPIL), which in most cases was to

species level unless the specimen was a juvenile, damaged, or otherwise unidentifiable. The number of individuals of each taxon, excluding fragments, was recorded. A voucher collection was prepared, composed of representative individuals of each species not previously encountered in samples from the Chesapeake Bay region.

DATA ANALYSIS

All data generated as a result of laboratory analysis of macroinfauna samples were first coded on data sheets. Enumeration data were entered for each species according to site and strata. These data were reduced to a data summary report for each site, which included a taxonomic species list and benthic community parameters information. Archive data files of species identification and enumeration were prepared.

The QA and QC reports for the Chesapeake Bay samples are given in the Appendix.

The analytical methodologies utilized for this study were similar to those used in similar benthic community characterization reports prepared for other state and federal agency surveys. Macrofaunal characterization involves an evaluation of several biological community structure parameters (*e.g.*, species abundance, species composition and species diversity indices) during initial data reduction, followed by pattern and classification analysis for delineation of taxa assemblages. Since species are distributed along environmental gradients, there are generally no distinct boundaries between communities. However, the relationships between habitats and species assemblages often reflect the interactions of physical and biological factors and indicate major ecological trends.

Assemblage Structure

Several numerical indices were chosen for analysis and interpretation of the macrofaunal data. Selection was based primarily on the ability of the index to provide a meaningful summary of data, as well as the applicability of the index to the characterization of the benthic community. Infaunal abundance is reported as the total number of individuals per site and the total number of individuals per square meter (= density). Taxa

richness is reported as the total number and mean number of taxa represented in a given site collection.

Taxa diversity, which is often related to the ecological stability and environmental "quality" of the benthos, was estimated by the Shannon-Weaver Index (Pielou, 1966), according to the following formula:

$$H' = \sum_{i=1}^S p_i (\ln p_i)$$

where, S = is the number of taxa in the sample,

i = is the i 'th taxa in the sample, and

p_i = is the number of individuals of the i 'th taxa divided by the total number of individuals in the sample.

Taxa diversity within a given community is dependent upon the number of taxa present (taxa richness) and the distribution of all individuals among those taxa (equitability or evenness). In order to quantify and compare faunal equitability to taxa diversity for a given area, Pielou's Index J' (Pielou, 1966) was calculated as $J' = H'/\ln S$, where $\ln S = H'_{\max}$, or the maximum possible diversity, when all taxa are represented by the same number of individuals; thus, $J' = H' / H'_{\max}$.

HABITAT CHARACTERISTICS

Sediment data for the 69 stations are given in Table 2 and Figures 2, 3, 4, 5 and 6. Sediment composition at the 69 stations varied considerably from > 99% gravel+sand at stations 66, 72, 74, 80, 86, 87, 96, 102-107, 111, 113, 114, and 116 to > 90% silt+clay at stations 81, 84, 97, 112, 115, 118, 120, 124, 125, 128, and 130 (Table 2; Figures 2 and 3). The spatial distribution of sediments at the Chesapeake Bay stations is given in Figure 4. The total organic carbon (TOC) fraction of the sediment ranged from 0.01% at station 64 to 4.35% at station 93 (Table 2; Figure 5). The spatial distribution of sediment percent TOC is given in Figure 6.

BENTHIC COMMUNITY CHARACTERIZATION

Faunal Composition, Abundance, and Community Structure

Table 3 provides a complete phylogenetic listing for all sites as well as data on taxa abundance and site occurrence. Microsoft™ Excel 5.0 spreadsheets are being provided separately to NOAA which include: raw data on taxa abundance and density by site, a complete taxonomic listing with site abundance and occurrence, a major taxa table with overall taxa abundance, and an assemblage parameter table including data on number of taxa, density, taxa diversity and taxa evenness by site.

A total of 7,963 organisms, representing 115 taxa, were identified from the 69 stations (Table 4). Bivalves were the most numerous organisms present representing 44.2% of the total assemblage, followed in abundance by gastropods (26.6%) and polychaetes (17.2%). Polychaetes represented 38.3% of the total number of taxa followed by malacostracans (22.6%), bivalves (13.0%), and gastropods (8.7%)(Table 4).

The abundance of major taxonomic groups by station is given in Table 5. The number of taxa per site ranged from 0 at stations 67 and 68 to 28 at station 105. The number of organisms per site ranged from 0 at stations 67 and 68 to 4408 at station 90. The percent abundance of annelids, molluscs and arthropods at the 69 stations is given in Figure 7.

The dominant taxon collected from the samples was the bivalve, *Gemma gemma*, representing 42.7% of the total assemblage (Table 3). The gastropods, *Odostomia* (LPIL) and *Acteocina canaliculata*, were also abundant representing 16.1% and 10.1% of the total assemblage, respectively. The polychaetes, *Nereis succinea*, *Glycinde solitara*, and *Paraprionospio pinnata*, and the gastropod, *A. canaliculata* were the most widely distributed taxa being found at 67%, 62%, 61% and 61% of the sites, respectively (Table 3). The distribution of taxa representing > 10% of the total assemblage at each station is given in Table 6.

Station density and taxa richness data are given in Table 7 and Figures 8 and 9. Density per station exhibited considerable variation and ranged from 0 organisms·m⁻² at stations 67 and 68 to 110,200 organisms·m⁻² at station 90 (Table 7; Figure 8). Taxa richness also varied and ranged from 0 at stations 67 and 68 to 28 at station 105 (Table 7; Figure 9). Strata density and taxa richness data are given in Table 8 and Figures 10 and 11. Strata densities varied from 125.0 (SD = 90.1) organisms·m⁻² at station 27 to 36,816.7 (SD = 63,551.9) organisms·m⁻² at strata 26 (Table 8; Figure 10). Strata taxa richness varied from 3.3 (SD = 2.5) taxa per station to 22.3 (SD = 6.7) taxa per station (Table 8; Figure 11).

Strata taxa diversity and evenness are given in Table 8 and Figures 12 and 13. Taxa diversity (H') exhibited considerable variation and ranged from 0 at stations 67, 68, 84, and 92 to 2.83 at station 105 (Table 8; Figure 12). Taxa evenness (J) also exhibited considerable variation and ranged from 0 at stations 67, 68, 84, and 92 to 1.00.97 at station 77 (Table 8; Figure 13). The spatial distribution of taxa diversity for the Chesapeake Bay stations is given in Table 7 and Figure 14.

APPENDIX

QUALITY ASSURANCE STATEMENT

Client/Project NOAA

Work Assignment Title 1999 Chesapeake Bay

Work Assignment Number Task Number

Description of Data Set or Deliverable: 69 Benthic macroinvertebrate samples collected

August 24-September 21, 1998; Young Dredge grabs.

Description of audit and review activities: Judged accuracy rates were well above standard

levels for sorting and taxonomy. Laboratory QC reports were completed. Copies
of QC results follow (see attachment.) All taxonomic data were
entered into computer and printed. This list was checked for accuracy against
original taxonomic data sheets.

Description of outstanding issues or deficiencies which may affect data quality: None
